designs in nanoelectronics often lead to challenging simulation problems and include strong feedback couplings industry demands provisions for variability in order to guarantee quality and yield it also requires the incorporation of higher abstraction levels to allow for system simulation in order to shorten the design cycles while at the

same time preserving accuracy the methods developed here promote a methodology for circuit and system level modelling and simulation based on best practice rules which are used to deal with coupled electromagnetic field circuit heat problems as well as coupled electro thermal stress problems that emerge in nanoelectronic designs this book covers 1 advanced monolithic multirate co simulation techniques which are combined with envelope wavelet approaches to create efficient and robust simulation techniques for strongly coupled systems that exploit the different dynamics of sub systems within multiphysics problems and which allow designers to predict reliability and ageing 2 new generalized techniques in uncertainty quantification uq for coupled problems to include a variability capability such that robust design and optimization worst case analysis and yield estimation with tiny failure probabilities are possible including large deviations like 6 sigma 3 enhanced sparse parametric model order reduction techniques with a posteriori error estimation for coupled problems and for uq to reduce the complexity of the sub systems while ensuring that the operational and coupling parameters can still be varied and that the reduced models offer higher abstraction levels that can be efficiently simulated all the new algorithms produced were implemented transferred and tested by the eda vendor magwel validation was conducted on industrial designs provided by end users from the semiconductor industry who shared their feedback contributed to the measurements and supplied both material data and process data in closing a thorough comparison to measurements on real devices was made in order to demonstrate the algorithms industrial applicability

the importance of the energy and commodity markets has steadily increased since the first oil crisis the sustained use of energy and other resources has become a basic requirement for a company to competitively perform on the market the modeling analysis and assessment of dynamic production processes is often performed using simulation software while existing approaches mainly focus on the consideration of resource consumption variables based on metrologically collected data on operating states the aim of this work is to depict the energy consumption of production plants through the utilization of a continuous simulation approach in combination with a discrete approach for the modeling of material flows and supporting logistic processes the complex interactions between the material flow and the energy usage in

production can thus be simulated closer to reality especially the depiction of energy consumption peaks becomes possible an essential step towards reducing energy consumption in production is the optimization of the energy use of non value adding production phases
